SUMMARY

In Power BI, data transformation involves cleaning and preparing raw data using Power Query, while data modeling organizes the prepared data into meaningful relationships for accurate analysis and reporting.

The model contains tables such as List of Orders, Order Details, Sales Target, and Order Data.

- Data transformation: Data is prepared in Power Query by checking data types, cleaning inconsistencies, removing duplicates where appropriate, and ensuring fields are suitable for analysis.
- Data modeling: The tables are organized through relationships using common fields, such as order identifiers, to connect order information with detailed transactions and sales targets.
- Calculation logic: Measures can be used to calculate total sales, quantities, and target achievement, enabling comparisons between actual performance and sales targets.
- Reporting logic: The model supports interactive analysis through filters, charts, and summaries.
